

## Why is there a separation of algorithms, iterators and containers in C++ STL

[Ask Question](#)

I can't figure out why they have separated algorithms, iterators and containers in C++ STL. If it's a heavy use of templates everywhere, then we can have classes having all stuff in one place with template parameters.

Some text that I got explains that iterators helps algorithms to interact with containers data but what if containers expose some mechanism to access the

an  
 answer  
 would  
 be that  
 M  
 contain  
 ers +  
 N  
 algorithm  
 ms  
 would  
 normal  
 ly  
 require  
 M \*  
 N  
 pieces  
 of  
 code,  
 but  
 with  
 iterator  
 s  
 acting  
 as  
 "glue",  
 you  
 can  
 have  
 only M  
 + N  
 pieces  
 of  
 code. —

With  $M$  containers +  $N$  algorithms, one would normally need  $M * N$  pieces of code, but with iterators acting as "glue", this can be reduced to  $M + N$  pieces of code.

Example: run 2 algorithms on 3 containers

```
std::list<int> l;
std::vector<int> v;
std::array<int, 10> a;
```

```
auto l_conta = l.begin();
auto v_conta = v.begin();
auto a_conta = a.begin();
```

```
auto l_count = l.end();
auto v_count = v.end();
auto a_count = a.end();
```

You are calling only 2 different algorithms, and only have code for 3 containers. Each container passes the `begin()` and `end()` iterators to the container. Even though you have  $3 * 2$

pieces of  
functionality  
that need to  
be written.

For more  
containers  
and  
algorithms,  
this  
separation is  
an enormous  
reduction in  
the  
combinatorial  
explosion in  
code that  
would  
otherwise  
ensue: there  
are 5  
sequence  
containers, 8  
associative  
containers  
and 3  
container  
adapters in  
the STL, and  
there are  
almost 80  
algorithms in  
`<algorithm>`  
alone (not  
even  
counting  
those in  
`<numeric>` )  
so that you  
have only 16  
+ 80 instead  
of  $16 * 80$  ,  
an 13-fold  
reduction in  
code! (Of  
course, not  
every  
algorithm  
makes sense

The iterators can be divided into 5 categories (input, output, forward, bidirectional and random access), and some algorithms will delegate to specialized versions depending on the iterator capabilities. This will diminish the code reduction somewhat, but greatly improve efficiency by selecting the best adapted algorithm to the iterator at hand.

Note that the STL is not completely consistent in the separation:

- `std::list` has its own `sort` member function that uses implementation on specific details to sort itself, and
- `std::string` has an
